ABSTRACT

In this paper, a new rider-motorcycle system including front and rear suspensions is modeled using multi-body dynamics, and the stabilization control system is designed for the linearized reduced-order model. We have already modeled the rider-motorcycle system taking into account the lean angle of the rider’s upper torso. The front and rear suspensions will be necessary for dynamical analysis of a motorcycle in braking situations. For the derived dynamical model with the front and rear suspensions, the front-steering assist controller is designed utilizing $H_\infty$ control. By carrying out simulations, the driving stability of the rider-motorcycle system with the front-steering assist control is investigated.

Keywords: vehicle dynamics, motorcycle, front-steering assist control, modeling.

1 INTRODUCTION

Recently, electric stability control systems for four-wheel vehicles are well studied. A motorcycle may be required to implement one of these systems in the future. Realizing these systems will need not only wheel control but also stability control by front steering.

Detail simulation models for motorcycles have been developed based on Lagrange’s equation of motion [1], [2], [3], and it enables simulation of motorcycle dynamics with a commercial software. On the other hand, analyzing the dynamical system for designing a control system often requires an appropriate reduced-order model. We have already modeled the rider-motorcycle system using multi-body dynamics [4] taking into account the lean angle of the rider’s upper torso [5], [6]. It has been demonstrated that a front-steering assist control stabilizes the motorcycle against applied impulsive disturbance on the front wheel [5], [7], [8]. For driving in a straight line at a low speed, references [7] and [8] have experimentally verified the stabilization capability of the front-steering assist control. In braking situations, the front and rear suspensions will be necessary for dynamical analysis of a motorcycle.

In this paper, a new rider-motorcycle system including front and rear suspensions [1], [2], [3] is
modeled. And the stabilization control system is designed for the linearized reduced-order model in steady-state circular turning. In particular, the driving stability of the rider-motorcycle system is investigated under the condition when the pitting motion is occurred due to braking.

2 MODELING

2.1 The Rider-Motorcycle System

The ten-degree of freedom rider-motorcycle system [5] includes the lean motion of the rider’s upper torso: \( \theta_{wx} \) rotating around the x-axis of the rear frame of the motorcycle, the steering angle: \( \delta \) and the rotation of the front and the rear wheel. In addition to them, this model includes the compression angle of the rear suspension: \( \psi \) and the compression length of the front suspension: \( l_{UD} \), which are restrained with a spring and a damper respectively. The rider’s upper torso is connected to the handle with a spring and a damper.

The dynamical model of the rider-motorcycle system is shown in Figure 1. It consists of five bodies; the rear frame (the rear frame, the rider’s lower body, the engine and the fuel tank), the front frame (the front fork, the steering head and the handle bars), the rear wheel, the front wheel and the rider’s upper torso. Table 1 shows specifications of the model [9]. The notations of Figure 1 are as follows; \( A \): center of mass of the rear frame, \( U \): center of mass of the front frame, \( C \): center of mass of the rear wheel, \( D \): center of mass of the front wheel, \( W \): center of mass of the rider’s upper torso, \( m_A \): mass of the rear frame, \( m_U \): mass of the front frame, \( m_D \): mass of the rear wheel, \( m_W \): mass of the rider’s upper torso, \( P_r \): ground contact point of rear wheel, \( P_f \): ground contact point of front wheel, \( \lambda \): caster angle, \( \tau_{rr} \): driving/braking torque of rear wheel, \( \tau_{rf} \): driving/braking torque of rear wheel, \( \tau_{fr} \): braking torque of front wheel, and \( \tau_{rf} \): steering torque. The center of mass of each rigid body is defined as the origin of each standard coordinate system.

The generalized coordinate and the generalized velocity are defined as

\[
\mathbf{Q} = \begin{bmatrix}
R_{OA}^T & \Theta_{OA}^T & \delta & \theta_{wx} & \theta_r & \theta_f & \psi & l_{UD}
\end{bmatrix}^T,
\]

\[
\mathbf{S} = \begin{bmatrix}
\dot{R}_{OA}^T & \dot{\Theta}_{OA}^T & \dot{\delta} & \dot{\theta}_{wx} & \dot{\theta}_r & \dot{\theta}_f & \dot{\psi} & \dot{l}_{UD}
\end{bmatrix}^T,
\]

Where

\[
\mathbf{R}_{OA}^T = \begin{bmatrix} x_A & y_A & z_A \end{bmatrix} \quad \mathbf{\Theta}_{OA}^T = \begin{bmatrix} \theta_z & \theta_x & \theta_y \end{bmatrix} .
\]

The dynamical model has twelve degrees of freedom: the position \( \mathbf{R}_{OA} \) of the rear frame in the inertia coordinate system, the Euler angles \( \mathbf{\Theta}_{OA} \) of the rear frame, the steering angle \( \delta \), the roll angle of the rider’s upper torso \( \theta_{wx} \), the rotation angle of the rear wheel \( \theta_{wz} \), the rotation angle of the front wheel \( \theta_{cz} \), this model includes the compression angle of the rear suspension \( \psi \), the compression length of the front suspension: \( l_{UD} \).

Let \( \mathbf{C}_{OA} \) be a rotation matrix that completes the rotation of a vector from the inertia coordinate system to the \( A \) coordinate system. Then the relationship between the derivative of the generalized coordinate and the generalized velocity is given as follows

\[
\dot{\mathbf{Q}} = \frac{\partial \mathbf{H}}{\partial \mathbf{S}} \mathbf{S} = \left[ \mathbf{C}_{OA} \quad \mathbf{O}_{3 \times 3} \right] \begin{bmatrix} \mathbf{O}_{9 \times 3} \\ \mathbf{I}_9 \end{bmatrix} .
\]  

(2)

Introducing velocity vectors:

\[
\mathbf{\Lambda}_{Oi}^T = \begin{bmatrix} \mathbf{v}_{Oi}^T & \mathbf{\Omega}_{Oi}^T \end{bmatrix} , \quad (i : A, U, C, D \text{ and } W)
\]

(3)

and the angular velocity vectors:
\[ \Omega_{OA} = M_{OA} \cdot \dot{\Omega}_{OA} \]
\[ = C_y(\theta_1)^{-1} \cdot C_x(\theta_2)^{-1} \cdot \mathbf{e}_z \cdot \dot{\theta}_z + C_y(\theta_1)^{-1} \cdot \mathbf{e}_x \cdot \dot{\theta}_x + \mathbf{e}_y \cdot \dot{\theta}_y \]
\[ \Omega_{OU} = C_{AU}^{-1} \cdot \Omega_{OA} + \mathbf{e}_x \cdot \dot{\Theta} \]
\[ \Omega_{OW} = C_{AW}^{-1} \cdot \Omega_{OA} + \mathbf{e}_x \cdot \dot{\Theta}_{wx} \]
\[ \Omega_{OC} = C_{JC}^{-1} \cdot C_{JC} \cdot \mathbf{A} + \mathbf{e}_y \cdot (\dot{\psi} + \dot{\Theta}_f) \]
\[ \Omega_{OD} = C_{UD}^{-1} \cdot C_{AU}^{-1} \cdot \mathbf{A} + C_{UD}^{-1} \cdot \mathbf{e}_x \cdot \dot{\Theta} + \mathbf{e}_y \cdot \dot{\Theta}_f \]

(4)

the velocity matrix \( H \) is obtained with Jacobian as Equation (5).

\[
H = \begin{bmatrix}
I_3 & O_3 & O_{31} & O_{31} & O_{31} & O_{31} & O_{31}
O_3 & I_3 & O_{31} & O_{31} & O_{31} & O_{31} & O_{31}
C_{lw} & C_{lw} \cdot \mathbf{R}_{lw} & \mathbf{R}_{lw} \cdot \mathbf{e}_z & O_{31} & O_{31} & O_{31} & O_{31}
O_3 & C_{lw} & \mathbf{e}_z & O_{31} & O_{31} & O_{31} & O_{31}
C_{lw} & C_{lw} \cdot \mathbf{R}_{lw} & O_{31} & \mathbf{R}_{lw}^T \cdot \mathbf{e}_z & \mathbf{C}_{lw}^T \cdot \mathbf{R}_{lw} & \mathbf{e}_z & O_{31}
O_3 & C_{lw} & \mathbf{e}_z & O_{31} & \mathbf{e}_z & O_{31} & O_{31}
C_{lw} & C_{lw} \cdot \mathbf{R}_{lw} & O_{31} & \mathbf{R}_{lw}^T \cdot \mathbf{e}_z & \mathbf{C}_{lw}^T \cdot \mathbf{R}_{lw} & \mathbf{e}_z & O_{31}
O_3 & C_{lw} & \mathbf{e}_z & O_{31} & \mathbf{e}_z & O_{31} & O_{31}
C_{lw} \cdot \mathbf{R}_{lw}^T & C_{lw}^T \cdot \mathbf{C}_{lw} & \mathbf{C}_{lw}^T \cdot \mathbf{R}_{lw}^T + \mathbf{C}_{lw}^T \cdot \mathbf{R}_{lw} & \mathbf{e}_z & O_{31} & O_{31} & O_{31} & O_{31} & -C_{lw} \cdot \mathbf{e}_z
O_3 & C_{lw}^T \cdot \mathbf{R}_{lw} & \mathbf{e}_z & O_{31} & \mathbf{e}_z & O_{31} & O_{31}
\end{bmatrix}
\]

(5)

### 2.2 Forces and Torques of the Rigid Bodies

The forces \( \mathbf{F} \) and the torques \( \mathbf{N} \) to the rigid bodies are described as Equations (6) and (7) respectively.

\[
\mathbf{F}_{OA}' = C_{OA}^T \cdot \mathbf{F}_{OA} = -C_{OA}^T \cdot (m_A \cdot g \cdot \mathbf{e}_z) - \mathbf{F}_{AC}
\]
\[
\mathbf{F}_{OU}' = C_{OU}^T \cdot \mathbf{F}_{OU} = -C_{OU}^T \cdot (m_U \cdot g \cdot \mathbf{e}_z) - \mathbf{F}_{UD}
\]
\[
\mathbf{F}_{OW}' = C_{OW}^T \cdot \mathbf{F}_{OW} = -C_{OW}^T \cdot (m_W \cdot g \cdot \mathbf{e}_z)
\]
\[
\mathbf{F}_{OC}' = C_{OC}^T \cdot \mathbf{F}_{OC} = -C_{OC}^T \cdot (m_C \cdot g \cdot \mathbf{e}_z + \mathbf{f}_{pr}) + \mathbf{F}_{AC}
\]
\[
\mathbf{F}_{OD}' = C_{OD}^T \cdot \mathbf{F}_{OD} = -C_{OD}^T \cdot (m_D \cdot g \cdot \mathbf{e}_z + \mathbf{f}_{pf}) + \mathbf{F}_{UD}
\]

(6)

\[
\mathbf{N}_{OA}' = (\tau_{xp} - \tau_{sa}) \cdot \mathbf{e}_x - \tau_{rr} \cdot C_{AC}^{-1} \cdot \mathbf{e}_y - \tau_{rf} \cdot C_{AD}^{-1} \cdot \mathbf{e}_y - \mathbf{R}_{AC} \cdot \mathbf{F}_{AC}
\]
\[
\mathbf{N}_{OU}' = \tau_{zp} \cdot C_{WU}^{-1} \cdot \mathbf{e}_z - \tau_{j} \cdot \mathbf{e}_z + \tau_{jf} \cdot C_{UD}^{-1} \cdot \mathbf{e}_y - \mathbf{R}_{UD} \cdot \mathbf{F}_{UD}
\]
\[
\mathbf{N}_{OW}' = -(\tau_{xp} - \tau_{sa}) \cdot \mathbf{e}_x - \tau_{cp} \cdot \mathbf{e}_z + \tau_{f} \cdot C_{WU} \cdot \mathbf{e}_z
\]
\[
\mathbf{N}_{OC}' = \tau_{rr} \cdot \mathbf{e}_y + \tau_{cr} \cdot C_{OC}^{-1} \cdot \mathbf{e}_z + \mathbf{R}_{CP} \cdot C_{OC}^{-1} \cdot \mathbf{f}_{opq}
\]
\[
\mathbf{N}_{OD}' = \tau_{jf} \cdot \mathbf{e}_y + \tau_{j} \cdot C_{OD}^{-1} \cdot \mathbf{e}_z + \mathbf{R}_{CP} \cdot C_{OD}^{-1} \cdot \mathbf{f}_{opq}
\]

(7)
\( \tau_{yp} \) is the lean torque from the rider’s upper torso, \( \tau_{zp} \) is the reaction torque of the rider’s arm along with z-axis of rider’s upper torso, \( \tau_{za} \) is the lean torque of the motorcycle, and \( \tau_{zf} \) and \( \tau_{zr} \) are self-aligning torque from the rear wheel and the front wheel. ~ describes the notation of a skew symmetric matrix for exterior product.

\( F_{AC} \) and \( F_{UD} \) are interaction caused by front and rear suspensions. Figure 2 shows the displacement of suspensions. The rear suspension force is assumed to be proportional to the displacement of rear suspension: \( \Delta R_{AC} \). The front suspension force \( F_{AC} \) is simply described along the z-direction of the U coordinate.

\[
F_{AC} = C_{AC} \cdot \mathbf{e}_z \cdot \left( K_{cs} \cdot \Delta R_{AC} - C_{ds} \cdot \Delta R_{AC} \right)
\]

\[
f_{acr} \text{ and } f_{acr}\text{ in the equation (3) are the tire forces,}
\]

\[
f_{acr} = f_{cx} \cdot D_{OCxx} + f_{cy} \cdot D_{OCyy} + f_{cz} \cdot D_{OCzz} \cdot C_{OC} \cdot \mathbf{e}_y,
\]

where \( D_{OCxx} \) is the unit vector of the x-direction of the rear wheel:

\[
D_{OCxx} = \begin{bmatrix}
-\mathbf{e}_x \cdot C_{OC} \cdot \mathbf{e}_y \\
\mathbf{e}_z \cdot C_{OC} \cdot \mathbf{e}_y
\end{bmatrix}.
\]

In Equation (10), \( f_{cx} \) and \( f_{cy} \) are the longitudinal and the lateral tire force. As it discussed in Chapter 2, the nonlinear rider-motorcycle model has to be linearized for designing a stability control system. Referring to Magic Formula [3], [10], to include the nonlinear characteristics of tire cornering forces in the linearized model, the tire cornering forces can be expressed using hyperbolic tangent function [11]:

\[
f_{cx} = \mu_{\text{max}} \cdot \frac{\tanh(a_{\mu} \cdot \mathbf{e})}{a_{\mu} \cdot \mathbf{b}_{\mu}} \cdot f_{cz},
\]

\[
f_{cy} = \mu_{\text{max}} \cdot \left( c_{S11} \frac{F_{c}}{g} + c_{S12} \right) \cdot \tanh(a_{c1} \cdot \beta) + \left( c_{S21} \frac{F_{c}}{g} + c_{S22} \right) \cdot \frac{\tanh(a_{c2} \cdot \theta)}{a_{c2} \cdot \mathbf{b}_{c2}} \cdot \sqrt{1 - \left( \frac{f_{cz}}{f_{cz\text{max}}} \right)^2},
\]

\[
f_{cz} = K_{cz} \cdot \Delta R_{r} + C_{cz} \cdot \Delta \dot{R}_{r},
\]
where $\varepsilon$ is the slip rate, $a_{\mu}=25$, $b_{\mu}=1$, $a_{c1}=16$, $a_{c2}=1$, $a_{c3}=1.6$, $C_{S1}=60.64$, $C_{S12}=4435.84$, $C_{S21}=14.60$, $C_{S22}=73.00$, $K_c=150000$, $C_v=1000$. Figure 3 shows the characteristic of the rear tire force given as (12) and Magic Formula. The tire forces of the front wheel are derived similarly.

### 2.3 Equations of Motion

With the velocity matrix $H$, the equation of motion is expressed as

$$ M_{HO} \cdot \ddot{H} = F_H, $$

where $M_{HO}$ and $F_H$ represent the mass matrix and the force matrix:

$$ M_{HO} = \text{diag}(M_A, J_{OA}, M_U, J_{OU}, M_W, J_{OW}, M_C, J_{OC}, M_D, J_{OD}) $$

$$ F_H = \begin{bmatrix} \Gamma_{OA}^T & \Gamma_{OU}^T & \Gamma_{OW}^T & \Gamma_{OC}^T & \Gamma_{OD}^T \end{bmatrix} $$

$$ \Gamma_{oi} = \begin{bmatrix} F'_{oi} - \Omega_{oi} \cdot M_i \cdot V'_{oi} \\ N'_{oi} - \Omega_{oi} \cdot J_{oi} \cdot \Omega'_{oi} \end{bmatrix} $$

$$ M_i = m_i \cdot \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} $$

$$ J_{oi} = \begin{bmatrix} I_{ix} & 0 & 0 \\ 0 & I_{iy} & 0 \\ 0 & 0 & I_{iz} \end{bmatrix} $$

\((i : A, U, C, D \text{ and } W)\)

Rewriting Equation (13) with the generalized velocity, the equation of motion is obtained as

$$ M_S \cdot \dot{S} = F_S. $$

$M_S$ and $F_S$ are respectively the transformed mass matrix and the transformed force matrix:

$$ M_S = \left(\frac{\partial H}{\partial S}\right)^T \cdot M_{HO} \cdot \left(\frac{\partial H}{\partial S}\right) $$

$$ F_S = \left(\frac{\partial H}{\partial S}\right)^T \cdot \left( F_H - M_{HO} \cdot \frac{d}{dt} \left(\frac{\partial H}{\partial S}\right) \cdot S \right) $$
From the equations (2) and (16), the nonlinear state-space description is represented:

$$\dot{x} = A_s(x)x + B_s(x)u + E_s(x),$$

where

$$A_s = \begin{bmatrix}
O_{12} & \frac{\partial \mathbf{Q}}{\partial \mathbf{S}} \\
O_{12} & M_s^{-1} \frac{\partial F_s}{\partial \mathbf{S}}
\end{bmatrix} = \begin{bmatrix}
O_{12} & \text{diag}[C_{Qd}, I_3, 1, 1, 1, 1, 1] \\
O_{12} & M_s^{-1} \left(\frac{\partial H}{\partial \mathbf{S}}\right)^T \cdot M_{HO} \cdot \frac{d}{dt} \left(\frac{\partial H}{\partial \mathbf{S}}\right)
\end{bmatrix},$$

$$B_s = \begin{bmatrix}
O_{12 \times 3} \\
M_s^{-1} \cdot \frac{\partial F_s}{\partial \mathbf{u}}
\end{bmatrix}, E_s = \begin{bmatrix}
O_{12 \times 1}
\end{bmatrix}.$$

The state vector $x$ and the input vector $u$ are given as

$$x = \begin{bmatrix}
\mathbf{Q} \\
\mathbf{S}
\end{bmatrix}, \quad u = \begin{bmatrix}
\tau_{rr} \\
\tau_{rf} \\
\tau_f
\end{bmatrix} = \begin{bmatrix}
\tau_{rr} \\
\tau_{rf} \\
\tau_f + \tau_{fe}
\end{bmatrix}.$$ (19)

### 3 ANALYSIS OF THE LINEARIZED STATE-SPACE MODEL

#### 3.1 Linearized State-Space Model

To analyze eigenvalues and frequency responses, Equations (2) and (16), which give the nonlinear dynamical model, are linearized around an equilibrium point [5]. When $\mathbf{Q}_0$ and $\mathbf{S}_0$ is a set of the equilibrium point with the generalized coordinate and generalized velocity respectively, Equations (1), (2) and (17) are linearized as:

$$\begin{align*}
\mathbf{Q} &= \mathbf{Q}_0 + \Delta \mathbf{Q}, \quad \mathbf{S} = \mathbf{S}_0 + \Delta \mathbf{S}, \\
M_s &= M_{s_0} + \Delta M_s, \quad F_s = F_{s_0} + \Delta F_s,
\end{align*}$$

(20)

Using Equation (20), Equations (2) and (16) can be linearized:

$$\begin{align*}
\Delta \dot{\mathbf{Q}} &= \Delta \frac{\partial \mathbf{Q}}{\partial \mathbf{S}} \mathbf{S}_0 + \frac{\partial \mathbf{Q}}{\partial \mathbf{S}} \mathbf{S}_0 \Delta \mathbf{S}, \\
M_{s_0} \cdot \Delta \mathbf{S} &= \Delta F_s.
\end{align*}$$

(21)

(22)

Thus the linearized state-space description is derived

$$\Delta \dot{x} = A_i \Delta x + B_i \Delta u,$$

(23)

where

$$A_i = \begin{bmatrix}
\frac{d}{dt} \left(\frac{\partial \mathbf{Q}}{\partial \mathbf{S}} \mathbf{S}_0\right)^T & \frac{\partial \mathbf{Q}}{\partial \mathbf{S}} \mathbf{S}_0 \\
M_{s_0}^{-1} \frac{\partial F_s}{\partial \mathbf{Q}} \mathbf{S}_0 & M_{s_0}^{-1} \frac{\partial F_s}{\partial \mathbf{Q}} \mathbf{S}_0
\end{bmatrix}, \quad B_i = \begin{bmatrix}
O_{12 \times 3} \\
M_{s_0}^{-1} \cdot \frac{\partial F_s}{\partial \mathbf{u}} \mathbf{S}_0
\end{bmatrix}.$$ (24)
\[ \Delta x = \begin{bmatrix} \Delta Q \\ \Delta S \end{bmatrix}, \quad \Delta u = \begin{bmatrix} \Delta \tau_{rr} \\ \Delta \tau_{rf} \end{bmatrix}. \quad (25) \]

#### Figure 4
Frequency response of linearized steady-state circular turning model at velocity: 40 km/h, roll angle: 19.7 deg.
To derive a reduced-order model for designing the front-steering assist control system, the analysis is done by diagonalizing the system matrix \( A_l \). The eigenvalues of the matrix \( A_l \) of the linearized model in straight running and circular turning at the speed of 40 km/h are shown in Table 2. Figure 4 (a) and (b) show the frequency responses of the linearized circular turning model from steering torque \( \Delta \tau_f \) to the roll angle \( \Delta \theta \). Figure 4 (c) and (d) also show the frequency responses from steering torque \( \Delta \tau_f \) to the steering angle \( \Delta \delta \).

Real values \( \alpha_1 \) and \( \alpha_2 \) are the eigenvalues of capsize modes, which are related to the roll and steering, respectively. For complex values, \( \beta_1 \) is the eigenvalue of the weave mode and \( \beta_2 \) is the eigenvalue of the wobble mode. It is seen from Table 2 that the vibration mode of \( \beta_1 \) is stable in circular turning while that in straight running is stable. It is also seen that the peak of the frequency responses \( \beta_1 \) and \( \beta_2 \) are close to the weave mode \( \beta_1 \). The frequency response \( \beta_3 \) is identified as the eigenvalue of the rider’s upper torso mode [5]. The peak of the frequency responses \( \beta_4 \) and \( \beta_5 \) are also seen to be close to the eigenvalue of the wobble mode \( \beta_2 \). In Figure 4 (a) and (c), the gain of the frequency responses \( \beta_1 \) is small compared to \( \alpha_1 \) and \( \alpha_2 \). While the gain of the frequency responses \( \beta_2 \), \( \beta_4 \) and \( \beta_5 \) are small compared to the others in Figure 4 (b), those are not ignorable in Figure 4 (d).

From the result of frequency response analysis, ignoring the small contributors: \( \alpha_3 \), \( \alpha_4 \) and \( \alpha_5 \) in Table 2, 14\(^{th}\)-order model is obtained as shown in Figure 5. The 14\(^{th}\)-order model highly consists of the full-order model below 20 Hz for \( \Delta \theta / \Delta \tau_f \), and below 300Hz for \( \Delta \delta / \Delta \tau_f \). Without suspensions, it is shown that 12\(^{th}\)-order model is enough to express the full-order model [5]. The 12\(^{th}\)-order model does not include \( \beta_4 \).

### 3.3 The Front-Steering Assist Control System Design

Figure 6 shows the generalized plant to design \( H_\infty \) control system for the reduced-order model derived as shown in Figure 4. The feedback signal is the roll rate \( \Delta \theta \), and the output of the designed controller is the steering torque \( \Delta \tau_c \).

\( W_s \) and \( W_T \) are given as Equation (26) and Equation (27), respectively. \( W_N \) is fixed to 1.

\[
W_s = \frac{g_s \cdot \omega_n^2}{s^3 + 2 \zeta_d_s \omega_d s + \omega_d^2}
\]

\[
g_s = 2.24, \quad \omega_n = 36.1, \quad \zeta_d = 1, \quad \omega_d = 36.1
\]
The bode diagram of the $H_\infty$ controller designed using $W_S$, $W_T$ and $W_N$ is shown in Figure 7.

$$W_r = \frac{g_r \cdot \omega_i^2}{s^2 + 2\zeta_r \omega_i s + \omega_i^2}$$

$$g_r = 0.00023, \quad \omega_i = 7539.8, \quad \zeta_{dr} = 1. \quad (27)$$

The bode diagram of the $H_\infty$ controller designed using $W_S$, $W_T$ and $W_N$ is shown in Figure 7.

4 SIMULATIONS

It is supposed that existence of suspension in the model mainly affects the pitch motion of the motorcycle. Thus the performance of the front-steering assist control system should be verified when the motorcycle is in pitching motion. Figure 8 shows simulation results of the modes with and without suspensions.
From 2 s to 4 s, 50 Nm of the braking torque is given to the front and rear wheels. The friction coefficient is 0.8. In this situation, except for braking time, the motorcycle velocity is controlled by the PID control of the rear wheel torque. The initial velocity is 50 km/h and it decreases to 40 km/h after braking. During simulation, the steering torque is fixed to -6.5 Nm, which gives the roll angle 19.7 deg when the velocity is 40 km/h. Starting of braking at 2s and finishing of braking at 4s causes the pitching motion. From Figure 8 (a), it is seen that braking increases the
roll angle from 2 s to 4 s and oppositely releasing from braking decreases the roll angle. The roll angle of the model with suspensions varies more than that without suspensions. Figure 8 (b) shows the model with suspensions behaves by the large pitch rate than that without suspensions. To confirm the performance of the controller, an impulsive torque disturbance, which amplitude is 10 Nm and its width is 0.4 s, is given around steering axis at 5.5 sec. Other conditions are the same as the simulation shown in Figure 8. Figure 9 is the simulation result of the front-steering assist control system. Controller A is designed for the model with suspensions, while Controller B is designed for that without suspensions. When the impulsive disturbance is added, the roll angle without controller is increased 6.8 deg. As shown in Figure 9 (a), Controller A reduces the fluctuation of the roll angle 59%. Compared to Controller B, Controller A reduces the fluctuation 28.6% and settles the roll angle immediately. The steering control shown in Figure 9 (b) reduces fluctuation of the tire slip angles as shown in Figure 9 (c). Figure 9 (d) shows the input torque and its maximum value is -5.6 Nm.

5. CONCLUSIONS

Based on the multi-body dynamics theory, a dynamical model of the nonlinear twelve-degree freedom rider-motorcycle system is derived and linearized for the control design. The model consists of five rigid bodies, and includes not only the lean angle of the rider’s upper torso, but also the front and rear suspensions. This model enables consideration of pitching motion of the motorcycle caused by extension and compression of suspensions in braking situations. For circular turning at the velocity: 40 km/h, it is demonstrated that the front-steering assist control system designed for the model with suspension can immediately stabilize the motorcycle posture when the motorcycle behaves the pitching motion.

ACKNOWLEDGEMENTS

This Research is a part of Global GCOE program, the Center of Education and Research of Symbiotic, Safe and Secure System Design, Keio University. Authors would like to thank all who are involved for their support.
